### Parameters

Learnable deterministic parameters form the backbone of most trainable models; from unknown biases to weights in an ANN. More parameters mean more flexibility and training performance, not test performance.

degrees of freedom, overparameterization, generalization vs. memorization, identifiability, model selection

Parameters settle to meaningful values that yield reliable performance.

The model family is overly broad; overfitting precludes proper generalization.

Introduce a parameter to target card. How would you learn its value?

*"Imagine cutting the number of parameters in your model in half."*

*The troupe acquired more and more furniture, convinced each new piece would unlock a better show. Eventually the stage was so crowded they could barely move. The audience started applauding the furniture.*
