Symmetry

Symmetry, invariance, and conservation laws are higher principles that go hand in hand. They are powerful design constraints but incorporating them into a model can be difficult and the data must support it.

invariance, conservation laws, transformation groups, data augmentation, symmetry by architecture

Generalizes perfectly based on a higher principle.

Enforces equality where none should be.

Declare target card invariant in one of its variables.

"In your model, do you have one of symmetry, invariance, conservation but not the other?"

Adjusting the weights until both sides stilled took years to achieve and a minute to break. That instability was the key.
